If for an optical process [?]

1. the absorbtion is neglectable and
2. there is no change of the polarisation state of the radiation,

then the **relationship** between

- a) the oscillation of the electric current at a certain point in space and its
- b) induced electric field at a differnt point in space

stays **unchanged** if those two points in space are switched (those two points where the oscillation of the electric current and the measured electric field occure).

Thus there is a symmetry in the wave propagation of electromagnetic radiation, when the two locations between

- a) the source of radiation and
  - b) the observed detection
- are exchanged.

This is the **reversibility** of a radiation path, which in physics is called the “Reciprocity Principle”.

According to the physics of Wave Optics (Refraction Index, Dispersion and Absorbion, Light-speed), in a medium (matter) with refraction index

$$\eta^2 = \epsilon_r \mu_r \stackrel{dispersion}{=} \eta^2(\lambda) = \eta^2(\omega)$$

the frequency

$$\nu = \frac{\omega}{2\pi} = \frac{\eta k v}{2\pi} = \frac{\eta v_{vacuum}}{\lambda} \stackrel{=}{=} \frac{k c}{2\pi} = \frac{k}{2\pi} \frac{1}{\sqrt{\epsilon_0 \mu_0}} = \frac{c}{\lambda}$$

of the electromagnetic wave always remains unchanged if no external force is applied - it is **invariant**; while its wavelength  $\lambda = \frac{2\pi}{k}$  might shorten getting slower (where  $k$  = wavenumber, and  $v_{max} = c$  = lightspeed).

Hypothesis - **Reversibility of Information**: Therefore, energy  $E(\nu)$  is conserved - meaning: Information (energy) transmitted with the propagation of electromagnetic waves at a specific frequency remains stable because the optical process is reversible and thus has no change in entropy.
